**Abstract**—Code-based cryptography received attention after the NIST started the post-quantum cryptography standardization process in 2016. A central NP-hard problem is the binary syndrome decoding problem, on which the security of many code-based cryptosystems lies. The best known methods to solve this problem all stem from the information-set decoding strategy, first introduced by Prange in 1962. A recent line of work considers augmented versions of this strategy, with hints typically provided by side-channel information. In this work, we consider the integer syndrome decoding problem, where the integer syndrome is available but might be noisy. We study how the performance of the decoder is affected by the noise. We provide experimental results on cryptographic parameters for the BIKE and *Classic McEliece* cryptosystems, which are finalist and alternate candidates for the third round of the NIST standardization process, respectively.

**Index Terms**—Code-based cryptography, Syndrome decoding problem, Information-set decoding

## I. INTRODUCTION

*a) Post-quantum cryptography: on its way to become reality:* With the practical feasibility of a quantum computer of sufficient capacity getting more and more probable by the day, the threat posed by Shor’s algorithm [1] on number theory base cryptosystems grows as well. To address this threat, NIST began a standardization process in 2016 for post-quantum cryptography. The third round of this process ended in July 2020 when, in the Key Encapsulation Mechanism category, four finalists and five alternate candidates were announced. Among them, the *Classic McEliece* [2] and the BIKE [3] cryptosystems are two solutions based on error-correcting codes. Their security relies on the NP-hardness of the binary syndrome decoding problem (SDP) [4]. Given a parity-check matrix  $\mathbf{H}$  of a binary linear code, a binary syndrome vector  $\mathbf{s}^*$  and an integer  $t$ , the SDP consists in finding a binary vector  $\mathbf{x}$  of Hamming weight  $t$  such that  $\mathbf{H}\mathbf{x} = \mathbf{s}^*$ .

There are three main techniques for solving the SDP, i.e., statistical decoding [5], [6], [7], [8], information set decoding (ISD) [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21] and generalized inverse based decoding [22]. The best known strategy to solve the SDP is the ISD. Originally proposed by Prange in 1962 [23], it has been incrementally refined since by Lee and Brickell [10], Stern [11] and, more recently, by May, Meurer and Thomae [18] and by

Becker, Joux, May and Meurer [19]. The complexity of the ISD method has been used to better tune the parameters of the cryptosystems [24] according to the required security levels.

We would like to point out that SDP is the core hard problem of several code-based cryptosystems like the Niederreiter public-key encryption scheme [25], the FSB hash function [26], the SYND stream cipher [27] or the Stern identification scheme [28].

*b) Integer syndrome decoding: a variant of the syndrome decoding with side information:* One recent line of work considers modified versions of the SDP, for which additional information is available, for instance via side-channel analysis on implementations of the aforementioned cryptosystems. In [29], authors study the case where parts of the error are known, or only their Hamming weight. The case where the *integer syndrome*  $\mathbf{s}$  is available, instead of the binary one, as if the matrix-vector multiplication had been performed in the integer ring instead of the binary finite field, is considered in [30]. One method to obtain the integer syndrome is by laser fault injection attack, as presented in [31]. The problem one has to solve in this case is the integer syndrome decoding, referred to as  $\mathbb{N}$ -SDP, where the input is the parity-check matrix  $\mathbf{H}$ , the integer syndrome vector  $\mathbf{s}$  and the weight of the solution  $t$ . The same question is raised, whether  $\mathbf{H}\mathbf{x} = \mathbf{s}$  admits a solution of weight  $t$ . This problem can be tackled down by means of Integer Linear Programming [31] or probabilistic methods [32].

Another method of obtaining an integer syndrome, much more feasible and realistic than laser fault injection, is by side-channel analysis [33]. However, due to physical factors, the integer values of the syndrome might not be perfectly accurate. Hence, in the resulting problem, the  $\mathbb{N}$ -SDP in the presence of noise, we are given a noisy integer syndrome  $\tilde{\mathbf{s}} = \mathbf{s} + \epsilon$ , where  $\epsilon$  models the noise as a vector of random variables. The solution proposed in [33] uses a combination of ISD techniques and the score decoder from [32]. However, only simulations are provided to assess the performance of this proposal.

*Contributions:* In this article, we analyze in detail the algorithm proposed in [33], referred to as ISD-score decoder, and provide the following contributions. First, we demonstrate that the ISD-score decoder finds a solution to the  $\mathbb{N}$ -SDP

in the presence of noise with high probability, as long as the weight is sub-linear in  $n$ , more exactly,  $t \leq O\left(\frac{n-k}{\log(n-k)}\right)$ , where  $n$  is the length of the code and  $k$  the dimension. We consider two noise models, present in several schemes/scenarios, *i.e.*, Binomial centered in zero and Bernoulli variables. We demonstrate that the ISD-score decoder can tolerate noise levels that are linear in the weight of the solution  $t$ . For that we partially build our demonstration on the techniques used in [32]. We incorporate the noise models into these techniques and, by using sharper inequalities, determine a much clearer condition for having a higher probability of success. One consequence of this new method is that when the noise is null and the ISD part is ignored, equivalently the ISD-score decoder boils down to the algorithm proposed in [32], the conditions we propose on the range of  $t$  for which the algorithm succeeds is larger than those from [32]. This gives a lower bound on the number of syndrome entries, or the number of rows in the parity-check matrix, required to find a solution, known as the information theoretic bound.

### Outline of the article

In Section II we introduce the SDP and its variants,  $\mathbb{N}$  – SDP and  $\mathbb{N}$  – SDP in presence of noise. We also recall the cryptographic context where these problems occur. Section III begins by recalling the score decoder proposed in [33]. Then it analyzes the distribution of the discriminant function for the  $\mathbb{N}$  – SDP in presence of noise. The section ends with the description of the ISD-Score decoder. Next, we analyse the success probability of the ISD-Score decoder in Section IV. The theoretical results from this part are being compared with numerical values from our implementation of the algorithm in Section V. The section also makes a parallel between the efficiency of the ISD-Score decoder and other methods such as ILP. Finally, we conclude the article in Section VI.

## II. PRELIMINARIES

*a) Notations:* A finite field is denoted by  $\mathbb{F}$ , and the ring of integers by  $\mathbb{Z}$ . We write  $\mathbb{N}_n^* = \{1, \dots, n\}$  and  $\mathbb{Z}_{-n,n} = \{-n, \dots, 0, \dots, n\}$ . For  $p \in [0, 1]$  and  $n \in \mathbb{N}^*$  we denote the Bernoulli distribution by  $\mathcal{B}er(p)$  and the Binomial distribution by  $\mathcal{B}(n, p)$ . We denote by  $W(x)$  the Lambert W function. Matrices and vectors are written in bold capital, respectively small letters. We also use  $\text{HW}(c)$  to denote the Hamming weight of the vector  $c$ .

*b) Error correcting codes:* Let  $n$  and  $k$  be two positive integers such that  $k \leq n$ . An  $[n, k]$  linear code can be defined as a sub-vector space of dimension  $k$  of the vector space  $\mathbb{F}^n$ . A code can be specified either by its generator matrix  $\mathbf{G} \in \mathbb{F}^{k \times n}$  (a basis for the code), or by its parity-check matrix  $\mathbf{H} \in \mathbb{F}^{(n-k) \times n}$  (a basis for the dual code). The minimum distance, or the Hamming distance of a code  $\mathcal{C}$ , is the minimum of all  $\text{HW}(v)$  for  $v \in \mathcal{C}$ ,  $v \neq \mathbf{0}$ .

One of the main features of linear codes is their ability to decode noisy information/data. Several general decoding strategies exist, the syndrome decoding problem being one of them.

*c) Some variations of the Syndrome decoding problem:*

Let us start by formally defining the binary syndrome decoding problem.

**Definition 1 (SDP).**

**Inputs:**  $\mathbf{H} \in \mathbb{F}_2^{(n-k) \times n}$ ,  $\mathbf{s}^* \in \mathbb{F}_2^{n-k}$ ,  $t \in \mathbb{N}^*$ .

**Output:**  $\mathbf{x} \in \mathbb{F}_2^n$  s.t.  $\mathbf{H}\mathbf{x} = \mathbf{s}^*$ , and  $\text{HW}(\mathbf{x}) = t$ .

This problem is NP-Complete [4] and, as we shall quickly see, it constitutes the building block of code-based solution for post-quantum cryptography.

Now, a slightly different problem, the  $\mathbb{N}$  – SDP [31], [30], considers matrix-vector multiplication over the ring of integers instead of the binary field  $\mathbb{F}_2$ . Formally, the problem can be stated as follows.

**Definition 2 ( $\mathbb{N}$  – SDP).**

**Inputs:**  $\mathbf{H} \in \{0, 1\}^{(n-k) \times n}$ ,  $\mathbf{s} \in \mathbb{N}^{n-k}$ ,  $t \in \mathbb{N}^*$ .

**Output:**  $\mathbf{x} \in \{0, 1\}^n$ , s.t.  $\mathbf{H}\mathbf{x} = \mathbf{s}$ , and  $\text{HW}(\mathbf{x}) = t$ .

To define  $\mathbb{N}$  – SDP in the presence of noise as generally as possible, we model the noise  $\epsilon = (\epsilon_1, \dots, \epsilon_{n-k})$  as a vector of random variables  $\epsilon_i \sim \mathcal{D}$ , where  $\mathcal{D}$  is a discrete probability distribution. In the  $\mathbb{N}$  – SDP in the presence of noise, instead of having access to an instance of the  $\mathbb{N}$  – SDP, *i.e.*,  $(\mathbf{H}, \mathbf{s}, t)$ , we are given a noisy syndrome  $\tilde{\mathbf{s}} = \mathbf{s} + \epsilon$  and the value  $\mathbf{s}^* = \mathbf{s} \pmod{2}$  (component-wise).

**Definition 3 ( $\mathbb{N}$  – SDP in the presence of noise  $\epsilon$ ).**

**Inputs:**  $\mathbf{H} \in \{0, 1\}^{(n-k) \times n}$ ,  $\tilde{\mathbf{s}} \in \mathbb{Z}^{n-k}$

$\mathbf{s}^* \in \{0, 1\}^{n-k}$ ,  $t \in \mathbb{N}^*$

**Output:**  $\mathbf{x} \in \{0, 1\}^n$ , s.t.  $\mathbf{H}\mathbf{x} = \mathbf{s}^*$  with  $\text{HW}(\mathbf{x}) = t$

$\mathbf{s}^* = \mathbf{s} \pmod{2}$ , and  $\tilde{\mathbf{s}} = \mathbf{s} + \epsilon$ .

Remark that  $\mathbb{N}$  – SDP in presence of noise is the SDP with additional information. Under certain conditions, we hope that, given  $(\mathbf{H}, \mathbf{s}^*, t, \tilde{\mathbf{s}})$ , we can find  $\mathbf{x}$ , solution to the SDP. Also, when the noise is zero we face the classic  $\mathbb{N}$  – SDP.

*d) The Niederreiter encryption framework:* Both, *Classic McEliece* [2] and *BIKE* [3], are based on the Niederreiter encryption scheme [34]. The key generation, encryption and decryption functions of the Niederreiter cryptosystem are given in Algorithms 1, 2 and 3 respectively.

---

### Algorithm 1 Niederreiter key generation

---

- 1: **function** KEYGEN( $n, k, t$ )
  - 2:  $\mathcal{C}$  an  $[n, k]$  code that corrects  $t$  errors
  - 3: A parity-check matrix of  $\mathcal{C}$ :  $\mathbf{H}$
  - 4: An  $n \times n$  permutation matrix  $\mathbf{P}$
  - 5: An  $(n - k) \times (n - k)$  invertible matrix  $\mathbf{S}$
  - 6: Compute  $\mathbf{H}_{\text{pub}} = \mathbf{SHP}$
  - 7:  $\text{pk} = (\mathbf{H}_{\text{pub}}, t)$
  - 8:  $\text{sk} = (\mathbf{S}, \mathbf{H}, \mathbf{P})$
  - 9: **return** (pk, sk)
-

---

**Algorithm 2** Niederreiter encryption

---

- 1: **function** ENCRYPT( $m$ ,  $pk$ )
  - 2: Encode  $m \rightarrow x$  with  $HW(x) = t$
  - 3: Compute  $s^* = H_{pub}x$
  - 4: **return**  $s^*$
- 

---

**Algorithm 3** Niederreiter decryption

---

- 1: **function** DECRYPT( $s^*$ ,  $sk$ )
  - 2: Compute  $x' = \text{Decode}(S^{-1}s^*, H)$
  - 3: Compute  $m$  from  $P^{-1}x'$
  - 4: **return**  $m$
- 

Recent message recovery attacks are pointing the encryption step, where the cipher-text is obtained from the multiplication of the public parity-check matrix  $H_{pub}$  and the secret error vector  $x$ . Hence, in [33], [35] the matrix-vector multiplication is targeted as leakage point (line 3 in Algorithm 2). We shall not insist here on the technical details that allow the derivation of the integer syndrome  $s$  or the noisy integer syndrome  $\tilde{s}$  from this matrix-vector computation. However, such an exploit is achievable, hence enabling one to tackle the  $\mathbb{N}$ -SDP or the  $\mathbb{N}$ -SDP in presence of noise, in order to retrieve the secret message.

The sets of  $(n, k, t)$  parameters defined in [2] and [3] are given in Table I.

TABLE I:  $(n, k, t)$  parameters for *Classic McEliece* and *BIKE*

	$n$	$k$	$t$
<i>Classic McEliece</i>	3488	2720	64
	4608	3360	96
	6688	5024	128
	8192	6528	128
<i>BIKE</i>	24646	12323	134
	49318	24659	199
	81946	40973	264

## III. ISD-SCORE DECODER

## A. Score decoder

The idea of assigning a score to each column was already used in for the  $\mathbb{N}$ -SDP in [33]. The objective is to distinguish columns of  $H$  in the support of the solution vector from columns which are outside the support. We shall begin by defining a score decoder, as introduced in [32], that proved to be particularly discriminant in the context of  $\mathbb{N}$ -SDP. For a better illustration of the nice features of the decoder in the presence of noise, we will express it in function of the noiseless decoder. As we shall see, this method allows not only to derive a particularly simple relation between those two, but also to deduce conditions on the tolerated noise level.

**Definition 4.** Let  $H \in \{0, 1\}^{(n-k) \times n}$ ,  $s \in \mathbb{N}^{n-k}$  and  $t \in \mathbb{Z}^*$  be the input of  $\mathbb{N}$ -SDP. Then define the score of a column:

$$\forall i \in \mathbb{N}_n^* \quad \psi_i(s) = \sum_{\ell=1}^{n-k} (h_{\ell,i}s_{\ell} + (1 - h_{\ell,i})(t - s_{\ell})). \quad (1)$$

For the  $\mathbb{N}$ -SDP in the presence of noise we shall use  $\psi_i(\tilde{s})$ . The next result, rephrased from [32], expresses the capability of the score decoder to distinguish between columns in the support of the solution vector from columns which are outside the support.

**Theorem 1.** Let  $H \in \{0, 1\}^{(n-k) \times n}$  be a random matrix, with distribution given by  $h_{j,i} \sim \text{Ber}(\frac{1}{2})$  and  $s \in \mathbb{N}^{n-k}$  such that  $\exists x \in \{0, 1\}^n$  with  $HW(x) = t$  satisfying  $Hx = s$ . Then  $\psi_i(s)$  follows the distribution

$$\psi_i(s) \sim \begin{cases} \mathcal{B}((n-k)t, \frac{1}{2}) & , i \notin \text{Supp}(x) \\ \mathcal{B}((n-k)(t-1), \frac{1}{2}) + n-k & , i \in \text{Supp}(x) \end{cases}$$

Moreover, the following holds

$$\begin{cases} \mathbb{E}(\psi_i(s)) = \frac{(n-k)t}{2}, & \text{for } i \notin \text{Supp}(x) \\ \mathbb{E}(\psi_i(s)) = \frac{(n-k)t}{2} + \frac{n-k}{2}, & \text{for } i \in \text{Supp}(x) \end{cases}$$
$$\begin{cases} \text{Var}(\psi_i(s)) = \frac{(n-k)t}{4} & \text{for } i \notin \text{Supp}(x) \\ \text{Var}(\psi_i(s)) = \frac{(n-k)t}{4} - \frac{n-k}{4} & \text{for } i \in \text{Supp}(x) \end{cases}$$

The proof of this theorem is given in the appendix. The difference in the mean points out that  $\psi$  can be a distinguisher between positions in the support and outside the support of the vector  $x$ . In addition, the variance also differs, fact that will be used in the tail bounds. Moving forward, we will consider the noisy version of this problem in the next section.

## B. Score decoder in the presence of noise

As in [33], we make some assumptions on the noise considered here, i.e.,  $\epsilon_i$  are independent and identically distributed random variables, the noise does not depend on the distribution of the entries in  $H$  and the distribution  $\mathcal{D}$  is symmetric.

**Proposition 1** ([33]). For  $j \in \mathbb{Z}_{n-k}^*$  let  $\epsilon_j$  be i.i.d. discrete random variables following a symmetric distribution over the set  $\mathbb{Z}_{-d,d}$ , s.t.  $\epsilon_j$  and  $h_{i,j}$  are independent. Then

$$\text{Prob}(\psi_i(\tilde{s}) - \psi_i(s) = \alpha) = \text{Prob}\left(\sum_{j=1}^{n-k} \epsilon_j = \alpha\right).$$

*Proof.* Let  $Y_{\ell,i} = h_{\ell,i}\epsilon_{\ell} - (1 - h_{\ell,i})\epsilon_{\ell}$ . Then we have,

$$\begin{aligned} \psi_i(\tilde{s}) &= \sum_{\ell=1}^{n-k} (h_{\ell,i}(\tilde{s}_{\ell} + (1 - h_{\ell,i})(t - \tilde{s}_{\ell}))) \\ &= \sum_{\ell=1}^{n-k} (h_{\ell,i}(s_{\ell} + \epsilon_{\ell} + (1 - h_{\ell,i})(t - s_{\ell} - \epsilon_{\ell}))) \\ \psi_i(\tilde{s}) &= \psi_i(s) + \sum_{\ell=1}^{n-k} (h_{\ell,i}\epsilon_{\ell} - (1 - h_{\ell,i})\epsilon_{\ell}) \\ &= \psi_i(s) + \sum_{\ell=1}^{n-k} Y_{\ell,i} \end{aligned}$$

For any fixed value of  $\ell \in \mathbb{Z}_{n-k}^*$  we have  $\text{Prob}(Y_{\ell,i} = \alpha_{\ell}) = \text{Prob}(\epsilon_{\ell} = \alpha_{\ell})$  for any  $\alpha_{\ell} \in \mathbb{Z}_{-d,d}$  (using the symmetry property and the independence of  $h_{\ell,i}$  and  $\epsilon_{\ell}$ ). Hence  $Y_{\ell,i}$

follows the same distribution as  $\epsilon_\ell$ . Thus,  $\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s}) \in \mathbb{Z}_{-(n-k)d, (n-k)d}$  with probability distribution

$$\begin{aligned} \text{Prob}(\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s}) = \alpha) &= \text{Prob}\left(\sum_{\ell=1}^{n-k} Y_{\ell,i} = \alpha\right) \\ &= \text{Prob}\left(\sum_{j=1}^{n-k} \epsilon_j = \alpha\right) \end{aligned}$$

□

**Remark 1.** Notice that, to keep the difference  $\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s})$  as small as possible, it is not necessary that the  $\epsilon_i$  values are small. Indeed, the  $\epsilon_i$  values may be large, as long as  $\sum_{i=1}^{n-k} \epsilon_i$  is close to zero.

In the sequel, the following result will be needed for estimating the distinguishing capacity of the score function on the noisy syndrome.

**Proposition 2.** For any  $j \in \mathbb{Z}_{n-k}^*$  let  $\epsilon_j$  be a discrete random variable satisfying the conditions from Proposition 1 and let  $\sigma^2 = \text{Var}(\epsilon_j)$ . Let  $g(n, k, t)$  be a function in the parameters of  $\mathbb{N} - \text{SDP}$ . Then for any  $\alpha > \sigma\sqrt{(n-k)g(n, k, t)}$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s}) \geq \alpha) \leq \frac{1}{g(n, k, t)}. \quad (2)$$

*Proof.* Use Chebyshev inequality for the sum of  $\epsilon_j$  and the linearity of the variance. □

a) *The case of centered binomial noise:* For a centered binomial noise, we deduce the following.

**Corollary 1.** Let  $d \in \mathbb{N}$ . If  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$  then  $\psi_i(\tilde{\mathbf{s}})$  is a random variable that follows the distribution

- for  $i \notin \text{Supp}(\mathbf{x})$

$$\psi_i(\tilde{\mathbf{s}}) \sim -d(n-k) + \mathcal{B}\left((n-k)(t+2d), \frac{1}{2}\right)$$

- for  $i \in \text{Supp}(\mathbf{x})$

$$\psi_i(\tilde{\mathbf{s}}) \sim -(d-1)(n-k) + \mathcal{B}\left((n-k)(t-1+2d), \frac{1}{2}\right)$$

Moreover,  $\mathbb{E}(\psi_i(\tilde{\mathbf{s}})) = \mathbb{E}(\psi_i(\mathbf{s}))$  and  $\text{Var}(\psi_i(\tilde{\mathbf{s}})) = \text{Var}(\psi_i(\mathbf{s})) + (n-k)d/2$ .

To maintain the capability to distinguish between positions inside the support and positions outside the support, the noise parameter  $d$  from  $\mathcal{B}(2d, \frac{1}{2})$  should be restricted.

**Corollary 2.** Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$ . Then w.h.p. we have  $|\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s})| \leq \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ . Moreover, for any  $d \leq \frac{n-k}{8 \log \log(n-k)}$ , the function  $\psi(\tilde{\mathbf{s}})$  distinguishes positions in  $\text{Supp}(\mathbf{x})$  from positions outside  $\text{Supp}(\mathbf{x})$  w.h.p.

**Remark 2.** Notice that any function  $g(n, k, t)$  which tends to infinity when the parameters tend to infinity, is a valid choice. In particular,  $g(n, k, t) = \log \log t$  or  $g(n, k, t) = \log \log n$ .

Figure 1 shows the distribution of  $\psi_i$  values for different levels of noise, ranging from  $d = 0$ , i.e. the noiseless setting, to a very high noise of  $\mathcal{B}(2t, \frac{1}{2})$ . Notice that the distinguishing capability is much higher for the BIKE parameters, as shown in Figure 1a, than for the *Classic McEliece* parameters, as shown in Figure 1b.

b) *Bernoulli noise:* In the case of a noise of the form  $\epsilon_i \sim \text{Ber}(\{0, 1\}, 1/2)$ , we deduce the following.

**Proposition 3.** Let  $\epsilon_i \sim \text{Ber}(\{0, 1\}, 1/2)$ . Then  $\psi_i(\tilde{\mathbf{s}})$  is a random variable that follows the distribution  $\begin{cases} \mathcal{B}((n-k)(t+2), \frac{1}{2}) - (n-k), & i \notin \text{Supp}(\mathbf{x}) \\ \mathcal{B}((n-k)(t+1), \frac{1}{2}), & i \in \text{Supp}(\mathbf{x}) \end{cases}$ . Moreover,  $\mathbb{E}(\psi_i(\tilde{\mathbf{s}})) = \mathbb{E}(\psi_i(\mathbf{s}))$  and  $\text{Var}(\psi_i(\tilde{\mathbf{s}})) = \text{Var}(\psi_i(\mathbf{s})) + (n-k)/2$ .

Notice that, in the case of a Bernoulli type of noise, the behavior is equivalent to the case of a centered binomial noise. (equivalent to  $d = 1$  in Corollary 1). Indeed, the result in Proposition 3 is equivalent to the one given in Corollary 1 with  $d = 1$ .

### C. Combining ISD and score decoder

The idea in [33] was to boost the distinguishing capability of the score decoder with ISD-like techniques. To this end, the score decoder is integrated in the “permutation” step of the ISD method. Indeed, this method starts by performing a permutation on the columns of  $\mathbf{H}$  that will hopefully rearrange the solution in a useful way. More precisely, in the first ISD algorithm, the Prange decoder [23], a “good” permutation ( $\mathbf{\Pi}$ ) is one that satisfies  $\mathbf{\Pi}^{-1}\mathbf{x} = \begin{pmatrix} \mathbf{x}_1 \\ \mathbf{0} \end{pmatrix}$ . Hence, the initial system becomes  $\mathbf{H}\mathbf{\Pi}\mathbf{\Pi}^{-1}\mathbf{x} = \mathbf{s}^*$ . By Gaussian elimination on  $\mathbf{H}\mathbf{\Pi}$  one can find an invertible matrix  $\mathbf{A}$  s.t.  $\mathbf{A}\mathbf{H}\mathbf{\Pi} = (\mathbf{I} \parallel \mathbf{B})$ . Hence, the system becomes  $(\mathbf{I} \parallel \mathbf{B}) \begin{pmatrix} \mathbf{x}_1 \\ \mathbf{0} \end{pmatrix} = \mathbf{A}\mathbf{s}^*$  which yields  $\mathbf{x}_1 = \mathbf{A}\mathbf{s}^*$ . In the original ISD methods, permutations are sampled randomly until a “good” one is obtained. Thanks to the extra-information provided by  $\mathbf{s}$  or  $\tilde{\mathbf{s}}$ , the function  $\psi$  allows to construct a permutation which by no means is random. Indeed, we have seen that  $\psi$ , by its nature, allows one to distinguish between positions in the support of  $\mathbf{x}$  and positions outside. Hence, the underlying permutation, hopefully is a “good” permutation. As pointed out in [33], sorting the list of values  $\psi_i(\tilde{\mathbf{s}})$  in descending order is equivalent to generating a permutation  $\mathbf{\Pi}$ . Algorithm 4 finds a solution to the  $\mathbb{N} - \text{SDP}$  in the presence of noise as long as  $\mathbf{\Pi}$  is “good” enough.

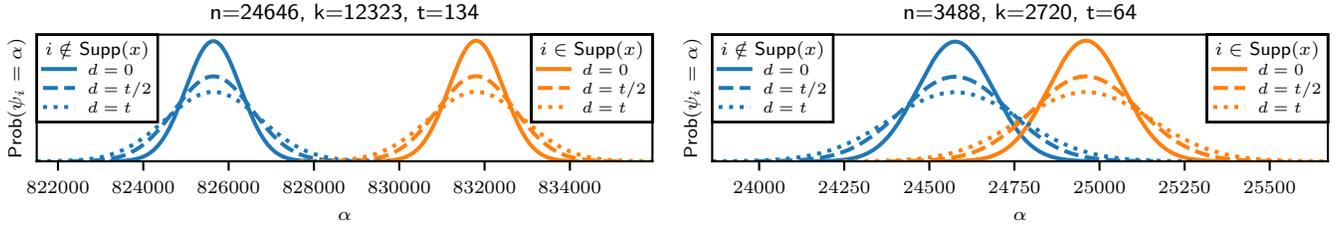

---

#### Algorithm 4 PRANGE SCORE DECODER( $\mathbf{H}, \mathbf{s}, t$ )

---

- 1: Compute  $\mathbf{\Pi}$  from the list  $\psi_i(\tilde{\mathbf{s}})$
  - 2: Compute  $\mathbf{A}^*, \mathbf{H}^* \leftarrow \text{rref}(\mathbf{H}\mathbf{\Pi})$
  - 3: **if**  $\text{HW}(\mathbf{A}^*\mathbf{s}^*) = t$  **then**
  - 4:   **return**  $\mathbf{x} = \mathbf{\Pi} \begin{pmatrix} \mathbf{A}^*\mathbf{s}^* \\ \mathbf{0}_{n-r} \end{pmatrix}$      $\triangleright r = \text{rank}(\mathbf{A})$
- 

The procedure  $\text{rref}(\mathbf{H}\mathbf{\Pi})$ , which stands for “reduced row echelon form”, is equivalent to performing a partial Gaussian

(a) Example parameters set of BIKE

(b) Example parameters set of *Classic McEliece*Fig. 1: Distribution of  $\psi_i$  for  $\epsilon \sim -d + \mathcal{B}(2d, \frac{1}{2})$ 

elimination over  $\mathbb{F}_2$ . Indeed, there is an  $(n-k) \times (n-k)$  non-singular matrix  $A^*$  such that,  $A^*H\Pi = \begin{bmatrix} I_r \\ \mathbf{0}_{n-k-r, r} \parallel B^* \end{bmatrix}$  where  $H\Pi = [A \parallel B]$  with  $A$  a  $(n-k) \times r$  matrix satisfying  $A^*A = \begin{bmatrix} I_r \\ \mathbf{0}_{n-k-r, r} \end{bmatrix}$ , and  $B^* = A^*B$ . In the of a full rank matrix  $A$  we have  $A^*A = I_{n-k}$ . From the description of the algorithm above, the following result can be deduced.

**Proposition 4** ([33]). PRANGE SCORE DECODER *outputs a valid solution as long as there exists at least one set  $L \subset \mathbb{N}_n^* \setminus \text{Supp}(\mathbf{x})$  with  $\#L \geq n-r$  such that  $\min\{\psi_i(\tilde{\mathbf{s}}), i \in \text{Supp}(\mathbf{x})\} > \max\{\psi_i(\tilde{\mathbf{x}}), i \in L\}$ .*

The overall time complexity of PRANGE SCORE DECODER is  $\mathcal{O}((n-k)^3)$ , since it is dominated by the partial Gaussian elimination, *i.e.* the computation of  $A^*$ .

Since the permutation  $\Pi$  might not move all the positions in the support of  $\mathbf{x}$  in the first  $n-k$  positions, more powerful ISD methods may be used, *e.g.* Lee-Brickell [10], Stern [11] or Dummer [13]. The idea is to allow a number of  $\delta$  positions from  $\text{Supp}(\mathbf{x})$  outside the first  $n-k$  positions. This is equivalent to extending PRANGE SCORE DECODER so that it covers error vectors with a more general pattern. The Lee-Brickell score decoder, where  $\delta$  positions are searched exhaustively, is thus proposed in [33] as a possible solution.

---

**Algorithm 5** Lee-Brickell Score Decoder ([33])

---

```

1: function LEE-BRICKELL SCORE DECODER( $H, \tilde{\mathbf{s}}, \mathbf{s}^*, t$ )
2:   Compute  $\Pi \leftarrow \text{SORT}(H, \tilde{\mathbf{s}}, t)$ 
3:   Set  $H\Pi = [A \parallel B]$ 
4:   Compute  $A^*, H^* \leftarrow \text{rref}(H\Pi)$  and  $B^* = A^*B$ 
5:   Compute  $\mathbf{s}' = A^*\mathbf{s}^*$ 
6:   if  $\text{HW}(\mathbf{s}') == t$  then
7:     return  $\mathbf{x} = \Pi(\mathbf{s}' \parallel \mathbf{0}_k)^t$ 
8:   else
9:     for  $i \leftarrow 1, \delta$  do
10:       $S = \text{Gener-Subsets}(\{1, \dots, k\}, i)$ 
11:      for  $E$  in  $S$  do
12:         $\mathbf{x}'' \leftarrow \text{Vector}(\{0, 1\}, k, E)$ 
13:         $\mathbf{x}' \leftarrow \mathbf{s}' - B^*\mathbf{x}''$ 
14:        if  $\text{HW}(\mathbf{x}') == t - i$  then
15:          return  $(\Pi(\mathbf{x}' \parallel \mathbf{x}'')^t, \Pi)$ 

```

---

When the Lee-Brickell variant is used and  $\delta = \mathcal{O}(1), k = \mathcal{O}(n)$ , the work factor of the resulting algorithm becomes polynomial in  $n$ .

**Proposition 5.** *The  $\delta$ -ISD-score decoder outputs a valid solution as long as there are at most  $\delta$  indices  $i \in \text{Supp}(\mathbf{x})$  with values  $\psi_i(\tilde{\mathbf{s}}) < \psi_j(\tilde{\mathbf{s}})$  with  $j$  in a set  $J \subset \mathbb{N}_n$  of cardinality  $n-k$ .*

#### IV. SUCCESS PROBABILITY OF THE ISD-SCORE DECODER

##### A. Main results

The following result gives a condition on the parameters for having a high probability of success for the ISD score decoder on the  $\mathbb{N}$ -SDP in presence of noise.

**Theorem 2.** *Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$ . If the interval  $\left[ \sqrt{\frac{t+2d}{n-k} W\left(\frac{n-t}{n-k-t+\delta+1} \frac{\epsilon\sqrt{2}}{\pi}\right)^2}, 1 - \sqrt{\frac{t+2d-1}{n-k} W\left(\frac{t}{\delta+1} \frac{2e}{\pi}\right)^2} \right]$  is non-empty, then w.h.p. the ISD-score decoder succeeds in finding a valid solution.*

To prove this theorem we shall use 3 steps. More precisely, we first give an estimation on the tails of the distributions  $\psi_i(\tilde{\mathbf{s}})$ , then we insert these results into a generic upper bound on the probability of success of the ISD-score decoder, and finally we study the range of parameters for which our conditions are valid.

1) *Tail bounds on the distribution of  $\psi_i(\tilde{\mathbf{s}})$  and  $\psi_i(\mathbf{s})$ .*: We will first give a result on the distribution of  $\psi_i(\mathbf{s})$ . As the average value of  $\psi_i(\mathbf{s})$  equals  $(n-k)t/2$ , for  $i \notin \text{Supp}(\mathbf{x})$  and  $(n-k)t/2 + (n-k)/2$ , for  $i \in \text{Supp}(\mathbf{x})$  we will fix a parameter  $\beta \in (0, 1)$  which gives the distance from the average value of  $\psi_i(\mathbf{s})$ . Our estimation can be stated as follows.

**Theorem 3.** *Let  $\beta \in (0, 1)$  and  $B_\beta = \frac{(n-k)t}{2} + \frac{\beta(n-k)}{2}$ . Then we have for  $i \notin \text{Supp}(\mathbf{x})$*

$$\text{Prob}(\psi_i(\mathbf{s}) \geq B_\beta) \leq \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t}{n-k}} e^{-\frac{n-k}{2t}\beta^2}, \quad (3)$$

for  $i \in \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\mathbf{s}) \leq B_\beta) \leq \frac{e}{\pi(1-\beta)} \sqrt{\frac{t-1}{n-k}} e^{-\frac{n-k}{2(t-1)}(1-\beta)^2}. \quad (4)$$

Moving forward, in the case of a binomial noise we have the following.

**Theorem 4.** Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$ ,  $\beta \in (0, 1)$  and  $B_\beta$  as previously defined. Then we have for  $i \notin \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \geq B_\beta) \leq \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}}, \quad (5)$$

for  $i \in \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \leq B_\beta) \leq \frac{e}{\pi(1-\beta)} \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}}. \quad (6)$$

The proof of these theorems is given in Appendix VII. Let us denote the upper bound by  $\text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, \beta)$  and by  $\text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, \beta)$  the upper bounds for the tail of  $\psi_i(\tilde{\mathbf{s}})$  in Theorem 4 for  $i \in \text{Supp}(\mathbf{x})$ , and  $i \notin \text{Supp}(\mathbf{x})$ , resp. Notice that taking  $d = 0$  in  $\text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, \beta)$  leads to the distribution of  $\psi(\mathbf{s})$ .

2) *A general bound on the success probability using tail estimations:* A general theorem regarding the success probability of ISD-score decoder can be stated. For that we suppose that the distribution  $\psi_i(\tilde{\mathbf{s}})$  when  $i \in \text{Supp}(\mathbf{x})$  has to be different from  $\psi_i(\tilde{\mathbf{s}})$  when  $i \notin \text{Supp}(\mathbf{x})$ , e.g., it is at least shifted. If not it is obvious that ISD-score decoder can not retrieve a valid solution with high probability.

**Theorem 5.** Let  $\psi_i(\tilde{\mathbf{s}})$  be random variables and  $f(n, k, t, d, B)$ ,  $g(n, k, t, d, B)$  be two functions s.t.

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \leq B) \leq e^{-f(n, k, t, d, B)}, \quad i \in \text{Supp}(\mathbf{x}) \quad (7)$$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \geq B) \leq e^{-g(n, k, t, d, B)}, \quad i \notin \text{Supp}(\mathbf{x}) \quad (8)$$

Then if it exists a value  $B^*$  s.t. the following conditions are satisfied

- $0 \leq 1 - \frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)} \leq 1$ ,
- $0 \leq 1 - \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)} \leq 1$ ,
- $\frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)} + \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)}$  is close to zero,

then w.h.p. ISD-score decoder succeeds in finding a valid solution.

Typically, the theorem gives a sufficient condition for having a high probability of success. Indeed, if one finds a value  $B_\beta$  for which the lower bound tends to 1 then Score function achieves its goal, namely to distinguish positions in the support of  $\mathbf{x}$  from those outside it. The proof of this result is given in the Appendix.

Combining the tail bounds on the distribution of  $\psi_i(\tilde{\mathbf{s}})$  with the condition on  $\beta^*$  for having a high probability of success enables the following result. Denote

$$\text{Lb}_{\text{Supp}(\mathbf{x})^c} = 1 - \frac{e(n-t)}{\sqrt{2\pi}\beta(n-k-t+\delta+1)} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}},$$

$$\text{Lb}_{\text{Supp}(\mathbf{x})} = 1 - \frac{e.t}{\pi(1-\beta)(\delta+1)} \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}}.$$

**Proposition 6.** Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$ . Then if it exists a value  $\beta^* \in (0, 1)$  s.t.  $\text{Lb}_{\text{Supp}(\mathbf{x})}, \text{Lb}_{\text{Supp}(\mathbf{x})^c} \in [0, 1]$  and

$\text{Lb}_{\text{Supp}(\mathbf{x})} \text{Lb}_{\text{Supp}(\mathbf{x})^c}$  is close to 1, then w.h.p. ISD-score decoder succeeds in finding a valid solution.

Putting  $d = 0$  in the above theorem implies the needed conditions for ISD-score decoder to retrieve a valid solution when a perfect syndrome is used.

**Corollary 3.** When  $d = 0$  and  $\delta = 0$  the condition on  $\beta^*$  simplifies to

- $0 \leq \frac{et}{\pi(1-\beta)} \sqrt{\frac{t}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2t}} \leq 1$ ,
- $0 \leq \frac{e(n-t)}{(\sqrt{2\pi}\beta)(n-k-t)} \sqrt{\frac{t}{n-k}} e^{-\frac{(n-k)\beta^2}{2t}} \leq 1$ ,
- $\frac{et}{\pi(1-\beta)} \sqrt{\frac{t}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2t}} + \frac{e(n-t)}{(\sqrt{2\pi}\beta)(n-k-t)} \sqrt{\frac{t}{n-k}} e^{-\frac{(n-k)\beta^2}{2t}}$  is close to zero,

To fairly compare with state-of-the-art techniques such as the algorithm in [32], which is only valid for the noiseless scenario, we adapted the conditions from [32] to the noise model considered here. This gives two similar functions in  $\beta$ , namely  $1 - \frac{n-t}{n-k-t} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}}$ , and  $1 - t \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}}$ . In Figure 2, we plot the modified functions from [32] (dashed lines) and  $\text{Lb}_{\text{Supp}(\mathbf{x})}, \text{Lb}_{\text{Supp}(\mathbf{x})^c}$  (solid lines).

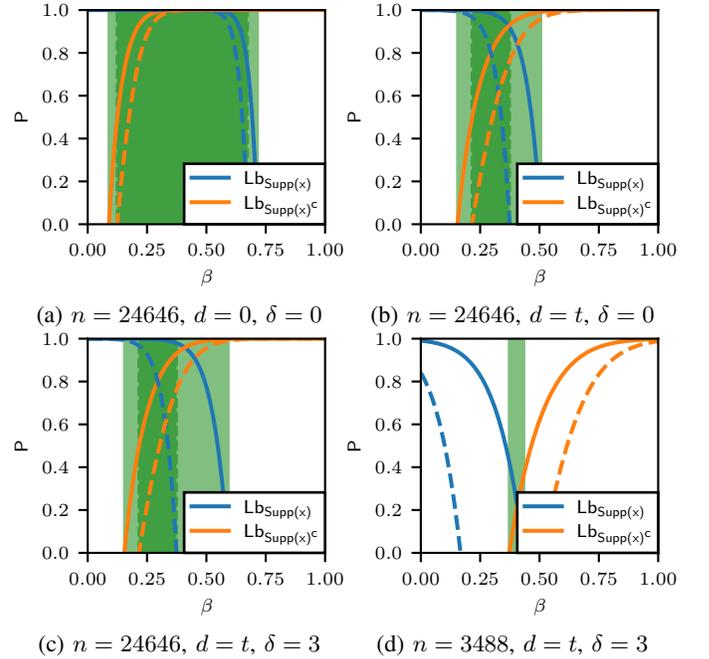

Fig. 2: Valid  $\beta$  interval from the bounds in [32] (dashed lines) and the proposed ones (solid lines)

In dark green and light green, the valid interval/region for the adapted functions from [32], and our functions, respectively, is represented. Notice that for all parameter sets and all noise levels considered here, our function offers a larger interval. Hence, this implies that for some sets of parameters, e.g., in Figure 2d, the interval is empty w.r.t. conditions in [32], while w.r.t. our conditions the interval exists.

3) *Range of valid parameters:* Here, we shall determine the conditions on the parameters such that the conditions in

Proposition 6 are satisfied. We will begin by determining the existence of  $\beta^*$ . We will need to denote by  $W(x)$  the Lambert  $W$  function.

**Proposition 7.** For any  $\beta \geq \sqrt{\frac{t+2d}{n-k} W\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2}$  we have that  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta) \leq 1$ , and for any  $\beta \leq 1 - \sqrt{\frac{t+2d-1}{n-k} W\left(\frac{t}{\delta+1} \frac{e}{\pi}\right)^2}$  we have that  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta) \leq 1$ .

Having both functions positive and strictly smaller than 1, at the same time, can be achieved as long the the interval defined by the two extreme points, in the previous Proposition is non-empty.

**Corollary 4.** As long as  $\sqrt{\frac{t+2d}{n-k} W\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2} \leq 1 - \sqrt{\frac{t+2d-1}{n-k} W\left(\frac{t}{\delta+1} \frac{e}{\pi}\right)^2}$  we have that  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta) \leq 1$  and  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta) \leq 1$ .

To give a more sensitive meaning of our result, we could approximate the value of the Lambert  $W$  function by  $W(m) = \log m - \log \log m + \frac{\log \log m}{\log m}$  as  $m$  tends to infinity. Using only the first term we define  $I_\beta = \left[ \sqrt{\frac{2(t+2d)}{n-k} \log \frac{n-t}{n-k-t+\delta+1}}, 1 - \sqrt{\frac{2(t+2d-1)}{n-k} \log \frac{t}{\delta+1}} \right]$ . Hence, we deduce the following result.

**Proposition 8.** If  $I_\beta \neq \emptyset$  then the probability of success of the ISD-score decoder is at least

$$\left(1 - \frac{e}{2\pi} \frac{1}{\sqrt{\log \frac{n-t}{n-k-t+\delta+1}}}\right) \left(1 - \frac{e}{\sqrt{2\pi}} \frac{1}{\sqrt{\log \frac{t}{\delta+1}}}\right).$$

Typically, our result gives a sub-interval where the conditions are safely satisfied. When simulations are to be performed, one could solve the inequalities in order to determine a more accurate interval. However, in using the Taylor series of the Lambert  $W$  function we can deduce the following.

**Corollary 5.** Let  $f_{n,k,t,\delta} = \frac{n-t}{n-k-t+\delta+1}$  and  $f_{t,\delta}^* = \frac{t}{\delta+1}$ . The extreme points of the interval where the first two conditions in Theorem 6 are satisfied, converges to  $\sqrt{\frac{t+2d}{n-k} \left(2 \log f_{n,k,t,\delta} - \log 2 \log f_{n,k,t,\delta} + \frac{\log 2 \log f_{n,k,t,\delta}}{2 \log f_{n,k,t,\delta}}\right)}$ , and  $1 - \sqrt{\frac{t+2d-1}{n-k} \left(2 \log f_{t,\delta}^* - \log 2 \log f_{t,\delta}^* + \frac{\log 2 \log f_{t,\delta}^*}{2 \log f_{t,\delta}^*}\right)}$ .

### B. Information-theoretic bounds

1) *Bounding the value of  $t$ :* To see how large the weight of the error  $t$  must be to have a non empty interval, the following rough estimate can be used.

**Theorem 6** (Upper bound on  $t$ ). Let  $k \leq n - t + \delta + 1 - (n - t)(\delta + 1)/t$  and  $d = ct/2$ . Then  $I_\beta \neq \emptyset$  as long as we have

$$t \leq \frac{n-k}{8(1+c)W\left(\frac{n-k}{8(1+c)(\delta+1)}\right)} \quad (9)$$

Moreover, when  $n \rightarrow \infty$ , we have that  $t \leq \mathcal{O}\left(\frac{n-k}{\log(n-k)}\right)$ .

Using a first term approximation for the Lambert  $W$  function near infinity, we obtain a threshold on  $t$ . More exactly this value can be approximated by  $\frac{n-k}{8(1+c) \log \frac{n-k}{8(1+c)(\delta+1)}}$ .

Now, recall that we have determined a preliminary condition on  $d$ , such that the  $\psi$  function can distinguish between positions in the support of the solution and outside it. This condition was  $d \leq \frac{n-k}{8 \log \log(n-k)}$ . Taking a slightly smaller noise level, e.g.  $d = \frac{n-k}{8 \log(n-k)} \leq \frac{n-k}{8 \log \log(n-k)}$  validates the choice in the hypothesis  $d = ct/2$ , as per Theorem 6  $t \leq \mathcal{O}\left(\frac{n-k}{\log(n-k)}\right)$ . Taking into account this condition and the hypothesis of Theorem 6, i.e.  $d = ct/2$ , we deduce the following upper bound on  $t$

$$d = \frac{ct}{2} \leq \frac{n-k}{8 \log t} \Rightarrow t \log t \leq \frac{n-k}{4c}. \quad (10)$$

This improves the constant term by  $t \leq \frac{n-k}{4cW\left(\frac{n-k}{4c}\right)}$ .

**Remark 3.** Notice that we cannot decrease the non-constant factors lower than what we have achieved here. More exactly we need to have at least  $t \log \frac{t}{\delta+1} \leq \frac{n-k}{2(1+c)}$  to possibly make the interval from Proposition 8 non-empty. Therefore, the minimum number of syndrome entries required for this algorithm to output a valid solution has to be at least  $2(1+c)t \log t / (\delta+1)$ . In the noiseless scenario, this becomes  $2t \log t$ .

2) *Bounding the required ratio of syndrome entries:* The existence of a value such that the ISD-score decoder succeeds in finding a solution using fewer syndrome entries could be deduced. It suffices to replace  $(n-k)$  with  $\gamma(n-k)$ , where  $\gamma \in (0, 1]$  represents the percentage of syndrome entries required to achieve a high probability. This value can be deduced from Theorem 6. Typically, given a number of rows  $n-k$ , the maximum value of  $t$  for which the success probability is close enough to 1 also determines the minimum number of required rows. More exactly, for a fixed value of  $t$  and  $n-k$ , we can compute  $\gamma(n-k)$ , the value for which  $t$  satisfies  $8t(1+c) \log \frac{t}{\delta+1} = \gamma(n-k)$ . By Theorem 6, with only  $\gamma(n-k)$  rows, one can recover a solution of weight at most  $t$  with high probability. Formally, the following holds.

**Corollary 6.** Let  $d = ct/2$  where  $c$  is a constant. Then the minimum quantity of information required by the ISD-score decoder to find a valid solution is  $4(1+c)t \log \frac{t}{\delta+1}$ . Moreover, in the noiseless scenario, the minimum quantity of information becomes  $4t \log \frac{t}{\delta+1}$ .

Consequently, we deduce that one could improve the constant term as pointed out in Remark 3, however not lower than  $2(1+c) \log \frac{t}{\delta+1}$ .

## V. EXPERIMENTAL RESULTS

The following experiments have been carried out on a standard laptop embedding an 8-core processor running at 1.6 GHz and 32 GB of RAM. The ILP solver we used is provided by the Scipy Python package [36] under the

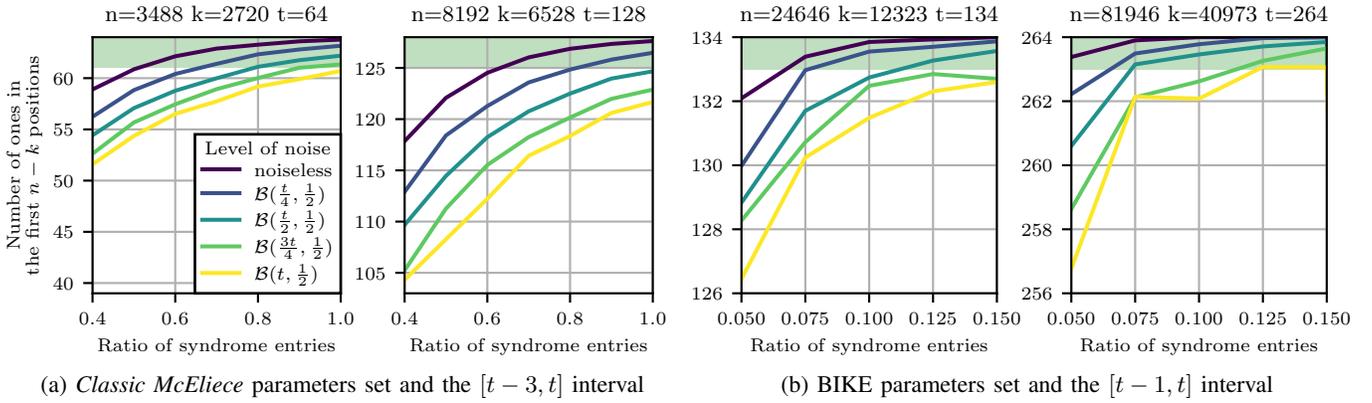

Fig. 3: Number of ones in the first  $n - k$  positions for some of the *Classic McEliece* and BIKE sets of parameters and different levels of a centered binomial noise.

`scipy.optimize.linprog` function. The score decoder is implemented using the Numpy Python package [37] to perform matrix computations.

#### A. Success probability and ratio of syndrome entries

For the results presented below, we set the  $(n, k, t)$  parameters according to the specifications of the *Classic McEliece* [2] and BIKE [3] cryptosystems.

The following experiments look at the number of syndrome entries required to bring  $t - \delta$  ones in the first  $n - k$  positions, as dictated by the ISD method. Results are shown in Figure 3, for both the *Classic McEliece* and the BIKE cryptosystems. Let us explain the meaning of the plots, when these are read horizontally. One way this could be read is as the weight of solutions retrieved by the ISD-Score decoder with probability 1. The green stripe represents the region corresponding to possible values of  $\delta$ . The value of  $\delta$  for the  $[t - \delta; t]$  interval is lower for the BIKE cryptosystem since it comes with much larger values of  $n$ , making the exhaustive search for the correct permutation much more costly. Conversely, we allow for  $\delta = 3$  in the case of *Classic McEliece* since the  $n$  values are smaller. For example, when  $n = 8192$  and noise level equal to  $t$  we can hope to retrieve solutions of weight at most 122 (which is smaller than the proposed parameters), while for the same length and noise smaller than  $t/2$  we can retrieve any solution of weight at most 128 using the ISD-score decoder using  $\delta = 3$ , or equivalently solutions of weight 125 using the Prange-score decoder. To summarize, except for the case  $n = 8192$  with noise levels strictly greater than  $t/2$ , all the plots suggests that the ISD-score decoder is able to retrieve with high probability a valid solution of weight  $t$  in presence of noise.

We can also read the plots vertically. This gives us the ratio of syndrome entries required to find a solution of given weight with high probability. The abscissa of the points of intersection between the curves and the green stripe gives minimum percentage of syndrome entries required in the ISD-score decoder to successfully retrieve a valid solution of weight  $t$ . For the BIKE cryptosystem, the ratio of syndrome

TABLE II: Theoretical lower bound on the ratio of syndrome entries necessary for the ISD-score decoder

$n$	noiseless	$\mathcal{B}(\frac{t}{4}, \frac{1}{2})$	$\mathcal{B}(\frac{t}{2}, \frac{1}{2})$	$\mathcal{B}(\frac{3t}{4}, \frac{1}{2})$	$\mathcal{B}(t, \frac{1}{2})$
<i>Classic McEliece</i>					
3488	0.46	0.58	0.69	0.81	0.92
4608	0.49	0.61	0.73	0.86	0.98
6688	0.53	0.67	0.80	0.93	1.00
8192	0.53	0.67	0.80	0.93	1.00
BIKE					
24646	0.09	0.11	0.14	0.16	0.18
49318	0.07	0.09	0.11	0.13	0.15
81946	0.06	0.08	0.09	0.11	0.13

entries required to bring at least  $t - 1$  ones in the first  $n - k$  positions ranges from 4.75% to 6.5%. For the *Classic McEliece* cryptosystem, the ratio of syndrome entries required to bring at least  $t - 3$  ones in the first  $n - k$  positions ranges from 48% to 62%. We have also computed the best theoretical lower bound we could hope for, *i.e.*, the percentage of syndrome entries should be at least  $\frac{2(1+\epsilon)t}{n-k} \log \frac{t}{\delta+1}$ . When comparing the experimental results shown in Figure 3 and Table II, we observe that theoretical values are around 10% smaller than the experimental values.

#### B. ILP solver and ISD-score decoder

a) *Percentage of required entries:* To compare the ILP solver with the ISD-score decoder we used the parameters for the *Classic McEliece* proposal. We decided to consider only the *Classic McEliece* because the execution time of the ILP solver for the smallest parameters of BIKE exceeded tens of minutes for a single instance of the  $\mathbb{N} - \text{SDP}$ . Obtaining in a reasonable time a solid statistical evidence of the performance of the ILP solver for BIKE, would assume a much more optimized implementation of the solver, which is not the main purpose of this article. The results for the ILP solver in the noiseless scenario are given in Figure 4. The success rate is computed for ten evenly spaced ratios ranging from 1 to 100%.

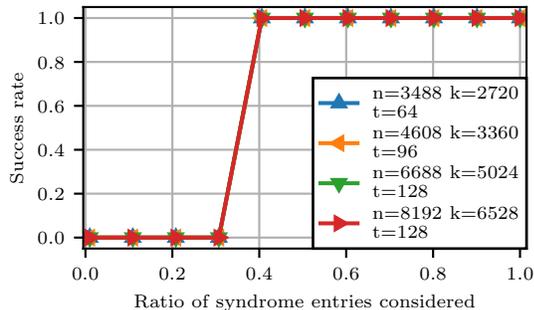

Fig. 4: Success rate of the ILP solver for the  $\mathbb{N} - \text{SDP}$  for four sets of parameters and different ratio of syndrome entries considered

We observe that the behavior is the same for all sets of parameters. When considering 30% of syndrome entries, the ILP solver failed at recovering the error vector ten times out of ten. Conversely, when considering 40% of syndrome entries, the ILP solver succeeded at recovering the error vector ten times out of ten. Hence, the main drawback of the ILP solver, when compared to the ISD-score decoder, is that the ILP cannot be used when only a small percentage of syndrome entries are known.

*b) Noisy setting:* In a noisy setting, the differences between the ILP solver and the ISD-score decoder is even more dramatic. Indeed, the ILP solver either succeeds in finding a valid solution, with  $t$  ones in the first  $t$  positions, or it fails. Conversely, the ISD-score decoder has a succeeds if  $t - \delta$  ones are in the first  $(n - k)$  positions, providing a much larger margin in the noisy setting.

Eventually, the permutation returned by the ISD-score decoder is always better than a random permutation. Therefore, one can always resort to exhaustive search afterwards.

*c) Computation time:* When comparing the time required by the two algorithms for retrieving a valid solution, we notice a significant gap between the two algorithms. From Figure 5 we can see that it takes less than 0.1 s for the ISD-score decoder, while for the ILP it takes at least 10 s for any of the parameters of the *Classic McEliece* scheme. Broadly speaking, the ILP solver is three orders of magnitude slower than the ISD-score decoder.

## VI. CONCLUSION

This article evaluated the efficiency of the score decoder for integer syndrome decoding in the presence of noise. We proved that, even in the presence of noise, this decoder is indeed able to successfully bring  $t - \delta$  ones in the first  $n - k$  positions, as required by the ISD-based methods. We then experimentally validate this capability considering the parameter sets of two post-quantum cryptosystems, *Classic McEliece* and BIKE. Future works could investigate other types of noise or improve the efficiency of the decoder, bringing it closer to the information-theoretic bound.

## APPENDIX

### Proof of Theorem 1

**Theorem (1).** *Let  $\mathbf{H} \in \{0, 1\}^{(n-k) \times n}$  be a random matrix, with distribution given by  $h_{j,i} \sim \mathcal{Ber}(\frac{1}{2})$  and  $\mathbf{s} \in \mathbb{N}^{n-k}$  such that  $\exists \mathbf{x} \in \{0, 1\}^n$  with  $\mathbf{HW}(\mathbf{x}) = \mathbf{t}$  satisfying  $\mathbf{H}\mathbf{x} = \mathbf{s}$ . Then  $\psi_i(\mathbf{s})$  follows the distribution*

$$\psi_i(\mathbf{s}) \sim \begin{cases} \mathcal{B}((n-k)t, \frac{1}{2}) & \text{for } i \notin \text{Supp}(\mathbf{x}) \\ n-k + \mathcal{B}((n-k)(t-1), \frac{1}{2}) & \text{for } i \in \text{Supp}(\mathbf{x}) \end{cases} \quad (11)$$

Moreover, the following holds

$$\begin{cases} \mathbb{E}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{2}, & \text{for } i \notin \text{Supp}(\mathbf{x}) \\ \mathbb{E}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{2} + \frac{n-k}{2}, & \text{for } i \in \text{Supp}(\mathbf{x}) \end{cases}$$

$$\begin{cases} \text{Var}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{4} & \text{for } i \notin \text{Supp}(\mathbf{x}) \\ \text{Var}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{4} - \frac{n-k}{4} & \text{for } i \in \text{Supp}(\mathbf{x}) \end{cases}$$

*Proof.* By definition 4 we have that

$$\psi_i(\mathbf{s}) = \sum_{\ell=1}^{n-k} (h_{\ell,i}s_{\ell} + (1 - h_{\ell,i})(t - s_{\ell})). \quad (12)$$

Let us denote  $X_\ell = h_{\ell,i}s_\ell + (1 - h_{\ell,i})(t - s_\ell)$ . As  $s_\ell = \sum_{j \in \text{Supp}(\mathbf{x})} h_{\ell,j}$  we deduce that

$$X_\ell = h_{\ell,i} \sum_{j \in \text{Supp}(\mathbf{x})} h_{\ell,j} + (1 - h_{\ell,i})(t - \sum_{j \in \text{Supp}(\mathbf{x})} h_{\ell,j}). \quad (13)$$

We have two cases :

- if  $i \notin \text{Supp}(\mathbf{x})$  then

$$X_\ell = \begin{cases} \sum_{j \in \text{Supp}(\mathbf{x})} h_{\ell,j} & = s_\ell & , \text{ if } h_{\ell,i} = 1 \\ t - \sum_{j \in \text{Supp}(\mathbf{x})} h_{\ell,j} & = t - s_\ell & , \text{ if } h_{\ell,i} = 0 \end{cases} \quad (14)$$

As  $s_\ell \sim \mathcal{B}(t, \frac{1}{2})$  we deduce that  $X_\ell \sim \mathcal{B}(t, \frac{1}{2})$  for all  $i \notin \text{Supp}(\mathbf{x})$ , and by independence we obtain  $\psi_i(\mathbf{s}) \sim \mathcal{B}((n-k)t, \frac{1}{2})$ , then  $\mathbb{E}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{2}$  and  $\text{Var}(\psi_i(\mathbf{s})) = \frac{(n-k)t}{4}$ .

- if  $i \in \text{Supp}(\mathbf{x})$  we have that  $s_\ell$  and  $h_{\ell,i}$  are dependent random variables. Hence we obtain

$$X_\ell = \begin{cases} 1 + \sum_{j \in \text{Supp}(\mathbf{x}) \setminus \{i\}} h_{\ell,j} & , \text{ if } h_{\ell,i} = 1 \\ 1 + (t-1) - \sum_{j \in \text{Supp}(\mathbf{x}) \setminus \{i\}} h_{\ell,j} & , \text{ if } h_{\ell,i} = 0 \end{cases} \quad (15)$$

As  $s_\ell - h_{\ell,i} \sim \mathcal{B}(t-1, \frac{1}{2})$  we deduce that  $X_\ell \sim 1 + \mathcal{B}(t-1, \frac{1}{2})$  for all  $i \in \text{Supp}(\mathbf{x})$ , and by independence of the variables  $X_\ell$  we obtain  $\psi_i(\mathbf{s}) \sim (n-k) + \mathcal{B}((n-k)(t-1), \frac{1}{2})$ .  $\square$

*Proof of Corollary 2*

**Corollary (2).** Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$ . Then w.h.p. we have  $|\psi_i(\tilde{\mathbf{s}}) - \psi_i(\mathbf{s})| \leq \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ . Moreover, for any  $d \leq \frac{n-k}{8 \log \log(n-k)}$ , the function  $\psi(\tilde{\mathbf{s}})$  distinguishes positions in  $\text{Supp}(\mathbf{x})$  from positions outside  $\text{Supp}(\mathbf{x})$  w.h.p.

*Proof.* Apply Proposition 2 and Corollary 1 to obtain the results. In order to determine the upper bound on  $d$ , we start by computing the intervals of confidence for  $\psi_i(\tilde{\mathbf{s}})$  by substituting  $g(n, k, y) = \log \log(n-k)$  in Proposition 2. This yields an interval  $I_{\tilde{\mathbf{s}}}(i)$  defined by the two extremal points  $\mathbb{E}(\psi_i(\tilde{\mathbf{s}})) - \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$  and  $\mathbb{E}(\psi_i(\tilde{\mathbf{s}})) + \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ .

More exactly we have

- $i \notin \text{Supp}(\mathbf{x})$  the following extremal points  $\frac{(n-k)t}{2} - \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ , and  $\frac{(n-k)t}{2} + \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$
- $i \in \text{Supp}(\mathbf{x})$  the following extremal points  $\frac{(n-k)t}{2} + \frac{n-k}{2} - \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ , and  $\frac{(n-k)t}{2} + \frac{n-k}{2} + \sqrt{\frac{d(n-k) \log \log(n-k)}{2}}$ .

Since we require that the two intervals should be disjoint, we require to have

$$2\sqrt{\frac{d(n-k) \log \log(n-k)}{2}} \leq \frac{n-k}{2} \quad (16)$$

Hence, we should have  $d \leq \frac{n-k}{8 \log \log(n-k)}$ .  $\square$

*Proof of Theorem 3 and Theorem 4*

Let us begin by giving a useful result on the tail of binomial distribution.

**Lemma 1** ([38]). Let  $X \sim \mathcal{B}(n, 1/2)$  and  $n/2 \leq \alpha \leq n$ . Then

$$\text{Prob}(X \geq \alpha) \leq \frac{\alpha + 1}{2\alpha - n + 1} \text{Prob}(X = \alpha). \quad (17)$$

**Lemma 2** ([32]). Let  $X \sim \mathcal{B}(n, 1/2)$  and  $\alpha \leq n/2$ . Then

$$\text{Prob}\left(X = \frac{n}{2} + \alpha\right) \leq \frac{e}{2\pi} \sqrt{\frac{n}{\frac{n^2}{4} - \alpha^2}} e^{-\frac{2\alpha^2}{n}}. \quad (18)$$

**Proposition 9.** Let  $X \sim \mathcal{B}(n, 1/2)$  and  $\alpha < n$ . Then

$$\text{Prob}\left(X \geq \frac{n}{2} + \frac{\alpha}{2}\right) \leq \frac{e}{2\pi} \left(1 + \frac{n+1}{\alpha+1}\right) \sqrt{\frac{n}{n^2 - \alpha^2}} e^{-\frac{\alpha^2}{2n}}. \quad (19)$$

*Proof.* Use Lemma 1 and 2.  $\square$

Now, we can proceed to the demonstration. Let us recall the result we want to prove.

**Theorem (3).** Let  $\beta \in (0, 1)$  and  $B_\beta = \frac{(n-k)t}{2} + \frac{\beta(n-k)}{2}$ . Then we have for  $i \notin \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\mathbf{s}) \geq B_\beta) \leq \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t}{n-k}} e^{-\frac{n-k}{2t}\beta^2}, \quad (20)$$

for  $i \in \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\mathbf{s}) \leq B_\beta) \leq \frac{e}{\pi(1-\beta)} \sqrt{\frac{t-1}{n-k}} e^{-\frac{n-k}{2(t-1)}(1-\beta)^2}. \quad (21)$$

*Proof.* Recall that

$$\psi_i(\mathbf{s}) \sim \begin{cases} \mathcal{B}((n-k)t, \frac{1}{2}) & \text{for } i \notin \text{Supp}(\mathbf{x}) \\ n-k + \mathcal{B}((n-k)(t-1), \frac{1}{2}) & \text{for } i \in \text{Supp}(\mathbf{x}) \end{cases}$$

By Proposition 9 this yields for  $i \notin \text{Supp}(\mathbf{x})$  we have that  $\text{Prob}(\psi_i(\mathbf{s}) \geq B_\beta)$  is smaller than or equal to

$$\leq \frac{e}{2\pi} \left(1 + \frac{(n-k)t+1}{(n-k)\beta+1}\right) \sqrt{\frac{(n-k)t}{(n-k)^2 t^2 - (n-k)^2 \beta^2}} e^{-\frac{(n-k)\beta^2}{2(n-k)t}} \quad (22)$$

$$= \frac{e}{2\pi} \left(1 + \frac{(n-k)t+1}{(n-k)\beta+1}\right) \sqrt{\frac{t}{(n-k)t^2 - (n-k)\beta^2}} e^{-\frac{(n-k)\beta^2}{2t}} \quad (23)$$

$$\leq \frac{e}{2\pi} \left(1 + \frac{t}{\beta}\right) \sqrt{\frac{t}{(n-k)(t^2 - \beta^2)}} e^{-\frac{(n-k)\beta^2}{2t}} \quad (24)$$

$$\leq \frac{e}{2\pi\beta} \sqrt{\frac{t+\beta}{t-\beta}} \sqrt{\frac{t}{(n-k)}} e^{-\frac{(n-k)\beta^2}{2t}} \quad (25)$$

$$\leq \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t}{(n-k)}} e^{-\frac{(n-k)\beta^2}{2t}} \quad (26)$$

For  $i \in \text{Supp}(\mathbf{x})$  we have that  $E(\psi_i(\mathbf{s})) = \frac{(n-k)t}{2} + \frac{n-k}{2}$ . Hence, by Proposition 9 we obtain that  $\text{Prob}(\psi_i(\mathbf{s}) \leq \frac{(n-k)t}{2} + \frac{(n-k)\beta}{2})$  is upper bounded by

$$\leq \frac{\frac{e}{2\pi} \left(1 + \frac{(n-k)(t-1)+1}{(n-k)(1-\beta)+1}\right) \sqrt{\frac{(n-k)(t-1)}{(n-k)^2(t-1)^2 - (n-k)^2(1-\beta)^2}}}{e^{\frac{(n-k)^2(1-\beta)^2}{2(n-k)(t-1)}}} \quad (27)$$

$$= \frac{\frac{e}{2\pi} \left(1 + \frac{(n-k)(t-1)+1}{(n-k)(1-\beta)+1}\right) \sqrt{\frac{t-1}{(n-k)((t-1)^2 - (1-\beta)^2)}}}{e^{\frac{(n-k)(1-\beta)^2}{2(t-1)}}} \quad (28)$$

$$\leq \frac{\frac{e}{2\pi} \left(1 + \frac{t-1}{1-\beta}\right) \sqrt{\frac{t-1}{(n-k)((t-1)^2 - (1-\beta)^2)}}}{e^{\frac{(n-k)(1-\beta)^2}{2(t-1)}}} \quad (29)$$

$$\leq \frac{e}{2\pi\beta} \sqrt{\frac{t-\beta}{t+\beta+2}} \sqrt{\frac{t-1}{(n-k)}} e^{-\frac{(n-k)(1-\beta)^2}{2(t-1)}} \quad (30)$$

$$\leq \frac{e}{2\pi\beta} \sqrt{\frac{t-1}{(n-k)}} e^{-\frac{(n-k)\beta^2}{2(t-1)}}. \quad (31)$$

□

Let us recall the second theorem to demonstrate.

**Theorem (4).** Let  $\epsilon_i \sim -d + \mathcal{B}(2d, \frac{1}{2})$  and  $\beta \in (0, 1)$ ,  $B_\beta = \frac{(n-k)t}{2} + \frac{\beta(n-k)}{2}$ . Then we have for  $i \notin \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \geq B_\beta) \leq \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}}, \quad (32)$$

for  $i \in \text{Supp}(\mathbf{x})$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \leq B_\beta) \leq \frac{e}{\pi(1-\beta)} \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}}. \quad (33)$$

*Proof.* Recall that we have

- for  $i \notin \text{Supp}(\mathbf{x})$

$$\psi_i(\tilde{\mathbf{s}}) \sim -d(n-k) + \mathcal{B}\left((n-k)(t+2d), \frac{1}{2}\right)$$

- for  $i \in \text{Supp}(\mathbf{x})$

$$\psi_i(\tilde{\mathbf{s}}) \sim -(d-1)(n-k) + \mathcal{B}\left((n-k)(t-1+2d), \frac{1}{2}\right)$$

The proof is thus identical with that of Theorem 3 by simply putting  $t' = t + 2d$  when  $i \notin \text{Supp}(\mathbf{x})$  and  $t' = t + 2d - 1$  when  $i \in \text{Supp}(\mathbf{x})$ . □

*Proof of Theorem 5*

**Theorem (5).** Let  $\psi_i(\tilde{\mathbf{s}})$  be random variables and  $f(n, k, t, d, B), g(n, k, t, d, B)$  be two functions s.t.

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \leq B) \leq e^{-f(n, k, t, d, B)}, \quad i \in \text{Supp}(\mathbf{x}) \quad (34)$$

$$\text{Prob}(\psi_i(\tilde{\mathbf{s}}) \geq B) \leq e^{-g(n, k, t, d, B)}, \quad i \notin \text{Supp}(\mathbf{x}) \quad (35)$$

Then if it exists a value  $B^*$  s.t. the following conditions are satisfied

- $0 \leq 1 - \frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)} \leq 1$ ,
- $0 \leq 1 - \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)} \leq 1$ ,
- $\frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)} + \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)}$  is close to zero,

then w.h.p. the ISD-score decoder succeeds in finding a valid solution.

*Proof.* Let  $X_B$  denote the number of indices  $j \in \text{Supp}(\mathbf{x})$  for which  $\psi_j(\tilde{\mathbf{s}}) \leq B$ , and  $Y_B$  the number of indices  $j \notin \text{Supp}(\mathbf{x})$  for which  $\psi_j(\tilde{\mathbf{s}}) \geq B$ . The probability of success of our algorithm equals

$$\begin{aligned} &= \sum_B \text{Prob}(X_B \leq \delta) \text{Prob}(Y_B \leq n - k - t + \delta) \\ &= \sum_B (1 - \text{Prob}(X_B \geq \delta + 1)) \cdot \\ &\quad (1 - \text{Prob}(Y_B \geq n - k - t + \delta + 1)) \\ &\geq \sum_B \left(1 - \frac{t}{\delta+1} e^{-f(n, k, t, d, B)}\right) \cdot \\ &\quad \left(1 - \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B)}\right). \end{aligned}$$

In the last equation we have used Markov's inequality. Also, the last sum is over those values  $B$  for which the two terms in the sum are both positive and smaller than 1. Now suppose that a  $B^*$  satisfying the required condition exists. Then the probability of success is

$$\begin{aligned} &\geq \left(1 - \frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)}\right) \cdot \\ &\quad \left(1 - \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)}\right) \\ &\geq 1 - \frac{t}{\delta+1} e^{-f(n, k, t, d, B^*)} - \\ &\quad \frac{n-t}{n-k-t+\delta+1} e^{-g(n, k, t, d, B^*)} \end{aligned}$$

□

*Range of valid parameters: proofs and comments*

The first useful results concerns the monotony of the two upper bounds.

**Lemma 3.** The functions  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta)$  and  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta)$  in  $\beta \in (0, 1)$ , are positive increasing, and positive decreasing, resp.

*Proof.* Let  $f(n, k, t, d, \beta) = \frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta)$  and  $g(n, k, t, d, \beta) = \frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta)$ . We have that both functions  $f, g$  are positive. We also have

$$\begin{aligned} \frac{\partial g(n, k, t, d, \beta)}{\partial \beta} &= \\ &= -\frac{(n-k)\beta^2 + (t+2d)}{\beta(t+2d)} g(n, k, t, d, \beta) \end{aligned}$$

$$\frac{\partial f(n, k, t, d, \beta)}{\partial \beta} = \frac{(n-k)(1-\beta)^2 + (t+2d-1)}{(1-\beta)(t+2d-1)} f(n, k, t, d, \beta).$$

Using the fact that  $f$  and  $g$  are positive we deduce the wanted result.  $\square$

Now we can demonstrate Proposition 7. Let us first recall this result.

**Proposition (7).** For any  $\beta \geq \sqrt{\frac{t+2d}{n-k} W\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2}$  we have that  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta) \leq 1$ , and for any  $\beta \leq 1 - \sqrt{\frac{t+2d-1}{n-k} W\left(\frac{t}{\delta+1} \frac{e}{\pi}\right)^2}$  we have that  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta) \leq 1$ .

*Proof.* Let us consider the limit point  $\beta$  where the two functions equal 1. As the first function is decreasing we then obtain a lower bound on  $\beta$ .

$$\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta) = 1 \quad (36)$$

$$\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}} = 1 \quad (37)$$

$$\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2 \frac{t+2d}{(n-k)\beta^2} = e^{\frac{(n-k)\beta^2}{t+2d}} \quad (38)$$

By letting  $y = \frac{(n-k)\beta^2}{t+2d}$  we have

$$e^y y = \left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2, \quad (39)$$

admitting a real solution  $y = W\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2$ , where  $W$  is the Lambert W function. From this we deduce  $\beta = \sqrt{\frac{t+2d}{n-k} W\left(\frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}}\right)^2}$ . The second function is increasing hence, it gives an upper bound on  $\beta$ .

$$\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta) = 1 \quad (40)$$

$$\frac{t}{\delta+1} \frac{e}{\pi(1-\beta)} \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}} = 1 \quad (41)$$

$$\left(\frac{t}{\delta+1} \frac{e}{\pi}\right)^2 \frac{t+2d-1}{(n-k)(1-\beta)^2} = e^{\frac{(n-k)(1-\beta)^2}{t+2d-1}} \quad (42)$$

As in the first case we obtain  $1 - \beta = \sqrt{\frac{t+2d-1}{n-k} W\left(\frac{t}{\delta+1} \frac{e}{\pi}\right)^2}$ .  $\square$

Proposition 8 given a slightly weaker condition, however, it helps understanding the order of magnitude of the parameters. Let us demonstrate the result.

*Proof.* Let  $\beta \geq \beta_1 = \sqrt{2 \frac{t+2d}{n-k} \log \frac{n-t}{n-k-t+\delta+1}}$ . Then the quantity  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta)$  equals

$$= \frac{n-t}{n-k-t+\delta+1} \frac{e}{\sqrt{2\pi}\beta} \sqrt{\frac{t+2d}{n-k}} e^{-\frac{(n-k)\beta^2}{2(t+2d)}} \quad (43)$$

$$\leq \frac{n-t}{n-k-t+\delta+1} \frac{e}{2\pi \sqrt{\log \frac{n-t}{n-k-t+\delta+1}}} e^{-\log \frac{n-t}{n-k-t+\delta+1}} \quad (44)$$

$$= \frac{e}{2\pi} \frac{1}{\sqrt{\log \frac{n-t}{n-k-t+\delta+1}}}. \quad (45)$$

Let  $1 - \beta \geq \beta_2 = \sqrt{2 \frac{t+2d-1}{n-k} \log \frac{t}{\delta+1}}$ . Then the quantity  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta)$  equals

$$= \frac{t}{\delta+1} \frac{e}{\pi(1-\beta)} \sqrt{\frac{t+2d-1}{n-k}} e^{-\frac{(n-k)(1-\beta)^2}{2(t+2d-1)}} \quad (46)$$

$$\leq \frac{e}{\sqrt{2\pi}} \frac{1}{\sqrt{\log \frac{t}{\delta+1}}}. \quad (47)$$

From this we deduce

$$\frac{\sqrt{2(t+2d)}}{\sqrt{n-k}} \sqrt{\log \frac{n-t}{n-k-t+\delta+1}} \leq \beta \quad (48)$$

$$\beta \leq 1 - \frac{\sqrt{2(t+2d-1)}}{\sqrt{n-k}} \sqrt{\log \frac{t}{\delta+1}}. \quad (49)$$

Now, suppose that  $[\beta_1, \beta_2]$  is non-empty and take  $\beta^* \in [\beta_1, \beta_2]$ . Since  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta)$  is increasing in  $\beta$ , this implies that  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta^*)$  is upper bounded by

$$\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta_2) = \frac{e}{\sqrt{2\pi}} \frac{1}{\sqrt{\log \frac{t}{\delta+1}}}. \quad (50)$$

Also, as  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta)$  is decreasing in  $\beta$  we have that  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta^*)$  is upper bounded by

$$\leq \frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta_1) \quad (51)$$

$$\leq \frac{e}{2\pi} \frac{1}{\sqrt{\log \frac{n-t}{n-k-t+\delta+1}}}. \quad (52)$$

Equations (50) and (51) implies that both function  $\frac{n-t}{n-k-t+\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})^c}(n, k, t, d, \beta)$ ,  $\frac{t}{\delta+1} \text{Ub}_{\text{Supp}(\mathbf{x})}(n, k, t, d, \beta)$  are smaller than 1 in  $\beta^*$  and that the probability of success is at least

$$\left(1 - \frac{e}{2\pi} \frac{1}{\sqrt{\log \frac{n-t}{n-k-t+\delta+1}}}\right) \left(1 - \frac{e}{\sqrt{2\pi}} \frac{1}{\sqrt{\log \frac{t}{\delta+1}}}\right). \quad (53)$$

$\square$

Proof of Theorem 6

*Proof.* Taking the simplified interval for  $\beta$ , the existence of this interval implies

$$\frac{\sqrt{2(t+2d)}}{\sqrt{n-k}} \sqrt{\log \frac{n-t}{n-k-t+\delta+1}} \leq 1 - \frac{\sqrt{2(t+2d-1)}}{\sqrt{n-k}} \sqrt{\log \frac{t}{\delta+1}} \quad (54)$$

$$\sqrt{\log \frac{n-t}{n-k-t+\delta+1}} + \sqrt{\log \frac{t}{\delta+1}} \leq \sqrt{\frac{n-k}{2(t+2d)}} \quad (55)$$

Using the condition on  $k$  we deduce

$$\sqrt{\log \frac{n-t}{n-k-t+\delta+1}} \leq \sqrt{\log \frac{n-t}{n - (n-t+\delta+1 - \frac{(n-t)(\delta+1)}{t}) - t + \delta + 1}} \quad (56)$$

$$\sqrt{\log \frac{n-t}{n-k-t+\delta+1}} \leq \sqrt{\log \frac{t}{\delta+1}}. \quad (57)$$

Hence, the following should hold

$$2\sqrt{\log \frac{t}{\delta+1}} \leq \sqrt{\frac{n-k}{2(1+c)t}} \quad (58)$$

$$\frac{t}{\delta+1} \log \frac{t}{\delta+1} \leq \frac{n-k}{8(1+c)(\delta+1)}, \quad (59)$$

which is satisfied as long as  $t \leq \frac{n-k}{8(1+c)W(\frac{n-k}{8(1+c)(\delta+1)})}$ .

The initial condition on  $k$  implies  $\frac{n-k}{t} \leq \frac{n-k+2\delta+2-\sqrt{(n-k+2\delta+2)^2-4n(\delta+1)}}{2}$  which is greater than or equal to  $\frac{n-k}{8(1+c)W(\frac{n-k}{8(1+c)(\delta+1)})}$ .

As for the asymptotic, use one term approximation for the LambertW function near infinity.  $\square$
